The abstract was presented at the 28th Annual Society for Maternal–Fetal Medicine Meeting, Dallas, TX, USA, January 2008 – Abstract #235

Design

A secondary analysis from a prospective cohort study of women undergoing first repeat caesarean section.

Setting

Department of Obstetrics and Gynecology, Stanford University, Stanford, CA, USA.

Results

Of the 127 women, primary hysterotomy closure was single layer in 56 and double layer in 71. Single-layer hysterotomy closure was associated with bladder adhesions at the time of repeat caesarean (24% versus 7%, \( P = 0.01 \)). Single-layer closure was associated in this study with a seven-fold increase in the odds of developing bladder adhesions (odds ratio, 6.96; 95% confidence interval, 1.72–28.1), regardless of other surgical techniques, previous labor, infection and age over 35 years. There was no association between single-layer closure and other pelvic or abdominal adhesions.

Conclusions

Primary single-layer hysterotomy closure may be associated with more frequent bladder adhesions during repeat caesarean deliveries. The severity and clinical implications of these adhesions should be assessed in large prospective trials.
